Topics

Part I

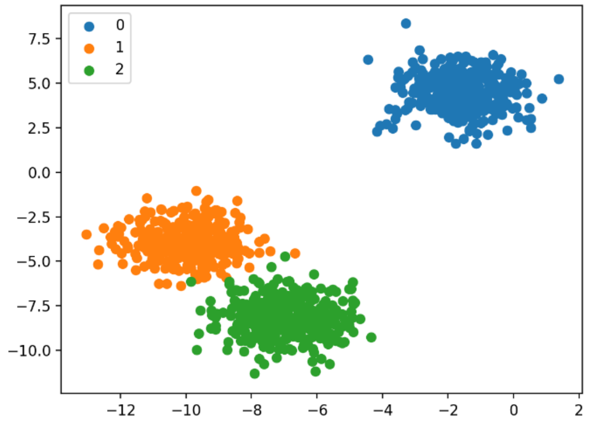
1. Linear probability model (LPM) vs Logistic regression
2. Sigmoid function
3. Logistic regression

Part II

1. Classification performance metrics
    a) Accuracy
    b) Precision
    c) Recall
    d) F1 score
    e) MCC
    f) ROC and AUC

		Predictions	
		0 negative	1 positive
Actual	0 negative	TN	FP
	1 positive	FN	TP

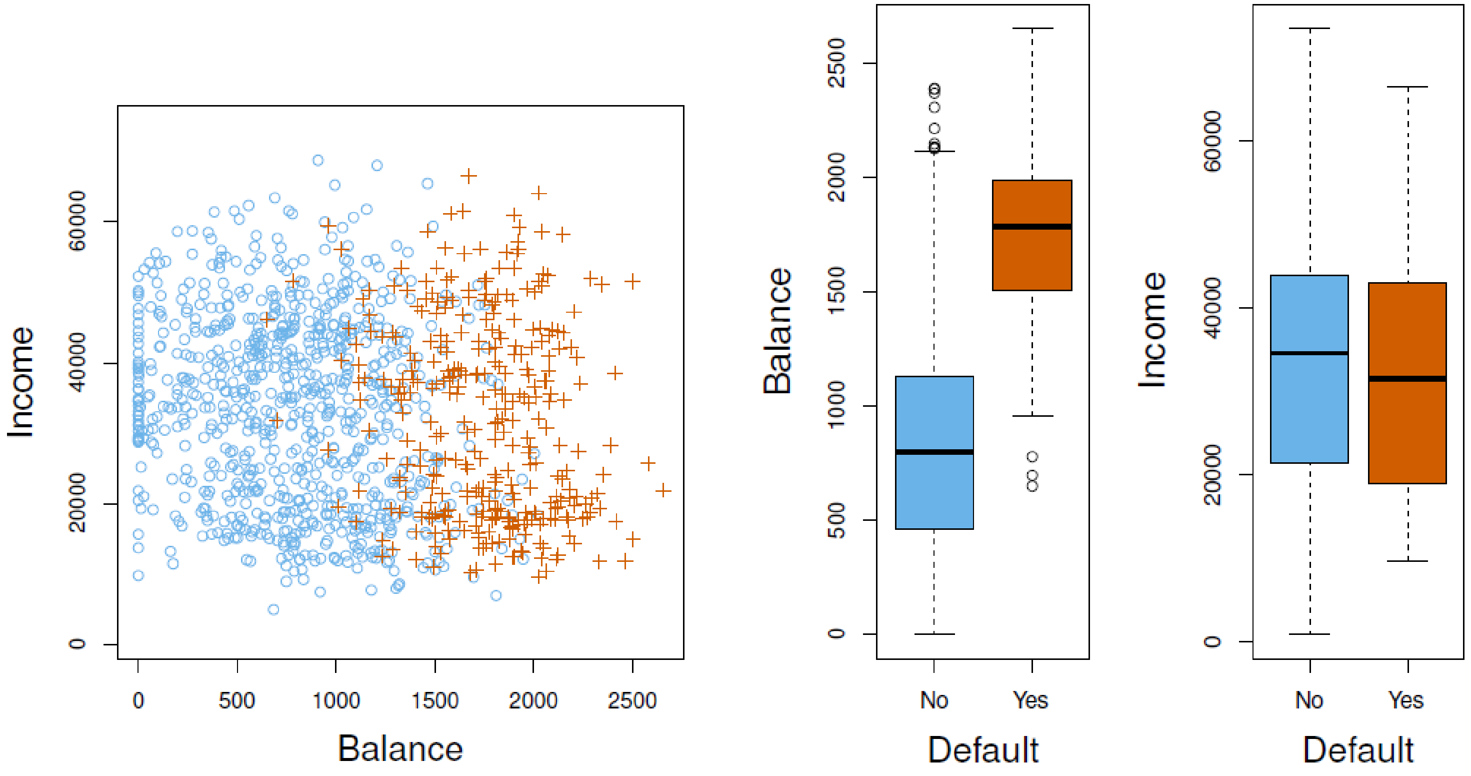
Classification



- Qualitative variables can be either nominal or ordinal.
- Qualitative variables are often referred to as **categorical.**
- **Classification** is the process of predicting categorical variables.
- Classification problems are quite common, perhaps even more than regression problems.
- **Examples:**
  - Financial instrument tranches (investment grade or junk)
  - Online transactions (fraudulent or not)
  - Loan application (approved or denied)
  - Credit card default (default or not)
  - Car insurance customers (high, medium, low risk)

Credit card default example

- Goal: Build a classifier that performs well in both train and test set.



Part I

Logistic Regression

Linear Probability Model (LPM) vs Logistic Regression

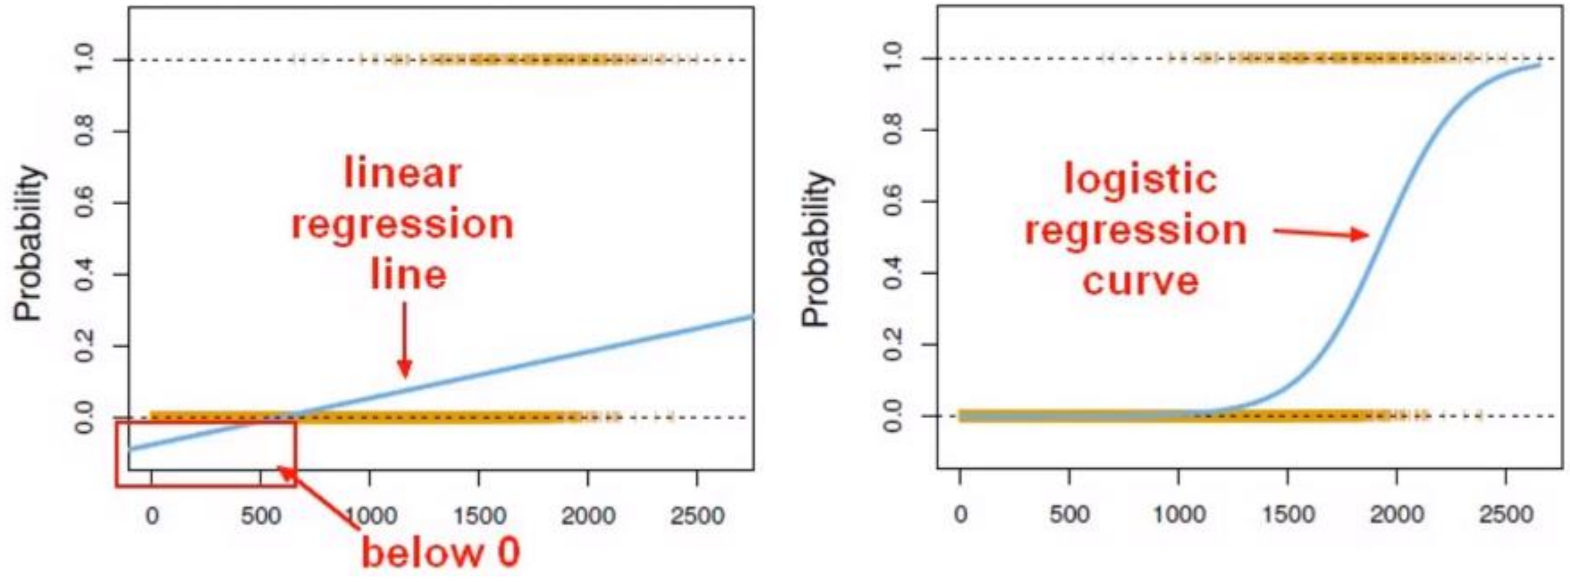
Starting with simple LPM : $y = \beta_0 + \beta_1 bal + \epsilon$ where, $Y = 1$ for default and 0 otherwise.

$$E(Y|bal) = \sum P(y_i|bal).y_i = \Pr(Y = 1|bal) = P(x) = \beta_0 + \beta_1 bal$$

- It seems that simple regression is perfect for this task,
- But what are the caveats?

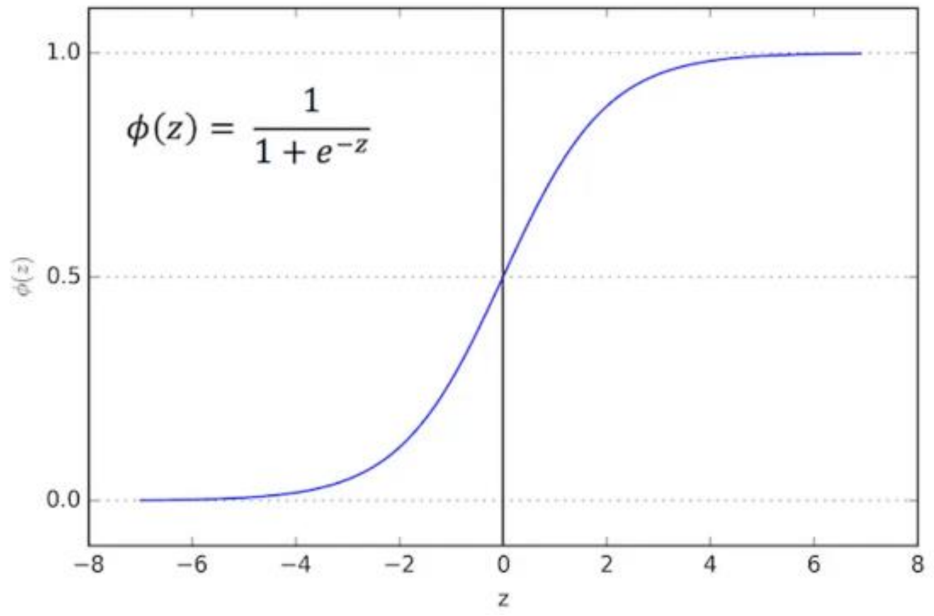
Linear Probability Model (LPM) vs Logistic Regression

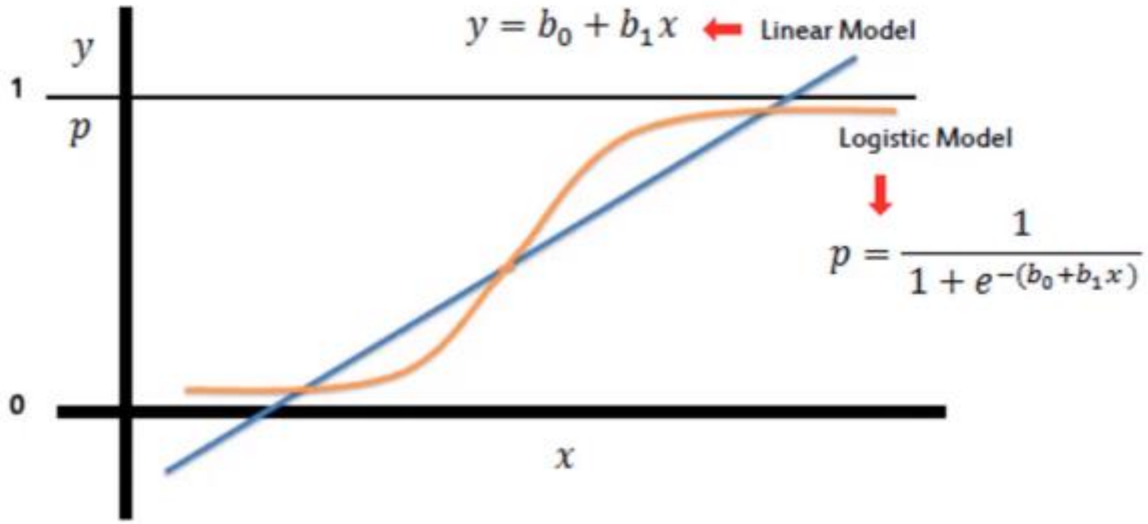
- What else? What if the data set is imbalanced?



Sigmoid Function

- We need a monotone mapping function that has a range of [0,1]

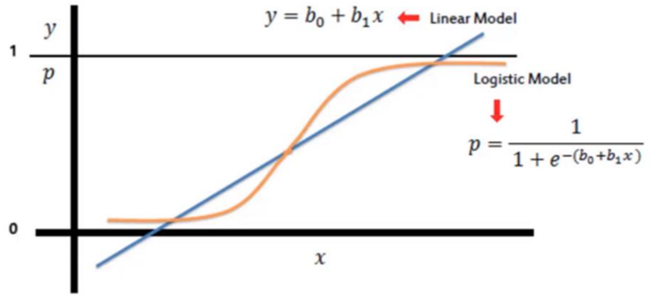




JON M. HUNTSMAN SCHOOL OF BUSINESS UtahStateUniversity

Logistic Regression (Model)

- The model: $f_{w,b}(X) = \frac{1}{1+e^{-(WX+b)}}$



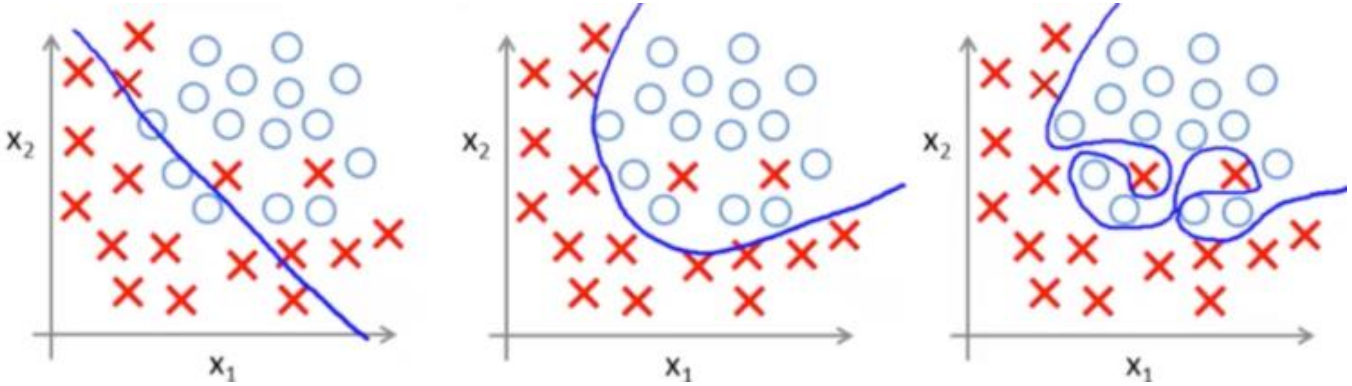
- In case of two classes, $f_{w,b}(X) = \Pr(Y = 1|x) = p(x)$.
- A bit of rearrangement gives

$$Log\left(\frac{p(X)}{1-p(x)}\right) = WX + b$$

- This monotone transformation is called the log odds or logit transformation of $p(x)$.
- Logistic regression ensures that our estimates always lie between 0 and 1

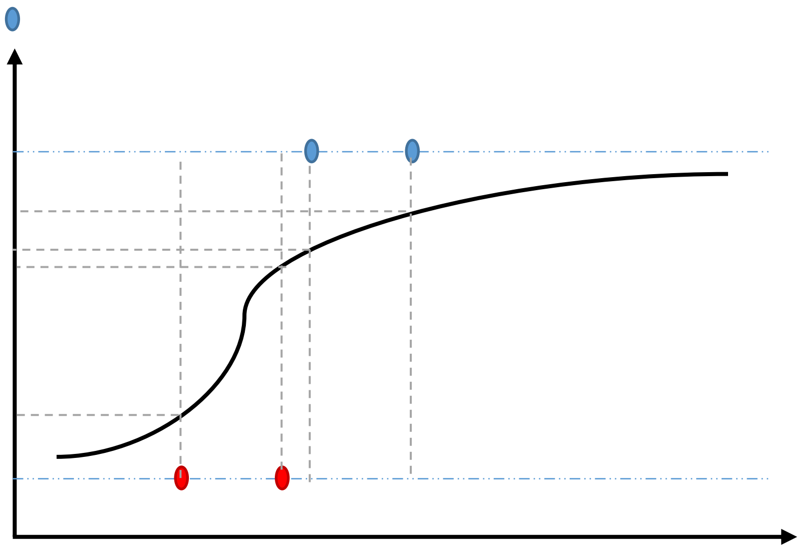
Logistic regression fit (Decision boundary)

- Depending on how we define $WX + b$, we can get any of the following fits from logistic regression classifier.

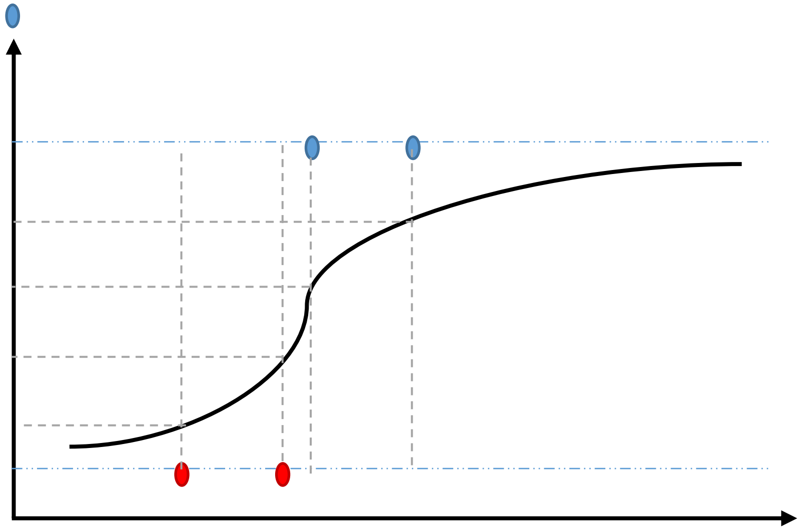


Logistic Regression (Maximum Likelihood)

- In logistic regression, instead of minimizing the average loss, we maximize the **likelihood** of the training data according to our model. This is called maximum likelihood estimation.
- What is the likelihood function?
- The likelihood function describes the joint probability of the observed data as a function of the parameters of the model.



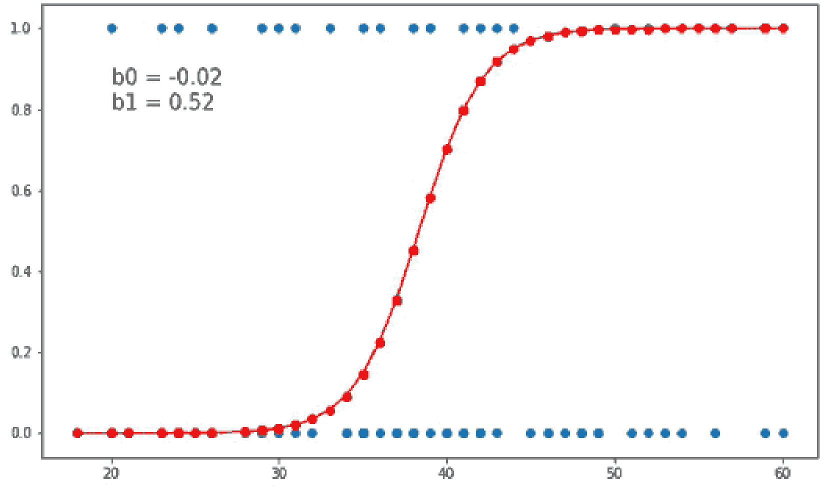
$$L = 0.9 * 0.8 \; * (1 - 0.75) * (1 - 0.2) = 0.144$$



$$L = 0.85 * 0.6 \; * (1 - 0.4) * (1 - 0.2) = 0.244$$

Logistic Regression (Maximum Likelihood)

- MLE in action!



$$f_{w^*,b^*}(X) = \frac{1}{1+e^{-(W^*X+b^*)}}$$

$$L_{w,b} = \prod_i f_{w,b}(x_i)^{y_i}\left(1 - f_{w,b}(x_i)\right)^{1-y_i}$$

Logistic Regression (Objective function)

- Maximizing the likelihood function:

$$Max\ \{L_{w,b} = \prod_i \ f_{w,b}(x_i)^{y_i} \left(1 - f_{w,b}(x_i)\right)^{1-y_i}\ \}$$

- **Solution**: In practice, it is more convenient to maximize the log-likelihood function. This log-likelihood maximization, gives us w^* and b^*. There is no closed form solution to this optimization problem. We need to use gradient descent.

- We are now ready to make **predictions**.

$$f_{w^*,b^*}(X) = \frac{1}{1+e^{-(W^*X+b^*)}}$$

- Depending on how we define the probability threshold, we can classify the observations. In practice, the choice of the threshold could be different depending on the problem.

Logistic regression output for credit card default example

$$P(default|bal, inc) = \frac{1}{1 + e^{-(b + w_1(bal) + w_2(inc))}}$$

		Predictions (Decision boundary)	
		0 No Default	**1 Default**
Actual	**0 No Default**	TN=1933	FP=3
	1 Default	FN=44	TP=20

Part II
Classification Performance Metrics

Confusion Matrix

		Predictions	
		0 negative	1 positive
Actual	0 negative	TN	FP*
	1 positive	FN**	TP

FP* Type I error
FN** Type II eror

		predicted class		
		class 1	class 2	class 3
actual class	class 1	True positives		
	class 2		True positives	
	class 3			True positives

Accuracy, Precision, Recall and F1score

$$Accuracy = \frac{TN + TP}{TN + TP + FN + FP}$$

		Predictions	
		0 negative	1 positive
Actual	0 negative	TN	FP
	1 positive	FN	TP

While **recall** expresses the ability to find all relevant instances in a dataset, **precision** expresses the proportion of the data points our model says was relevant were actually relevant.

$$Recall = \frac{TP}{TP + FN}$$

$$Precision = \frac{TP}{TP + FP}$$

$$F1\,Score = 2 * \frac{PR}{P + R}$$

F1 uses the **harmonic** mean instead of a simple average because it punishes extreme values.

MCC (Matthews Correlation Coefficient)

$$\mathrm{MCC} = \frac{\mathrm{TP} \cdot \mathrm{TN} - \mathrm{FP} \cdot \mathrm{FN}}{\sqrt{(\mathrm{TP}+\mathrm{FP})(\mathrm{TP}+\mathrm{FN})(\mathrm{TN}+\mathrm{FP})(\mathrm{TN}+\mathrm{FN})}}$$

- Accuracy and error rates are misleading for imbalanced data sets.
- Precision, recall or even f1 score will not take into account the true negatives (TN)
- MCC is one of the most informative metrics for any binary classifier.

		Predictions	
		0 negative	1 positive
Actual	0 negative	TN	FP
	1 positive	FN	TP

- MCC returns a value between -1 and +1.
  - ❑ +1 represents a perfect prediction,
  - ❑ 0 represents no better than a random prediction,
  - ❑ −1 indicates total misclassification

JON M. HUNTSMAN SCHOOL OF BUSINESS
